

Does it breathe on its own? Network integration through calendar time

integration mean $|\rho|$

effective dimensionality

volatility diagnostic: variance and lag-1 autocorrelation of the daily nightmare-index residual

what the instrument was doing: English reports and contributors per day

91-day rolling windows stepped every 7 days over English within-person deviations (windows below 150 reports are blank). The grey band is 120 circular rotations of the report block against the date axis, which keeps every window's size and local content structure but destroys calendar alignment. Violet lines mark the ten curated shocks. Read this figure as a warning before reading it as a result: the network tightens and effective dimensionality falls from 7.38 in the first window to 6.11 in the last (1.27 dimensions), while the bottom panel shows the platform growing underneath it, so contributor composition and any change in the annotation instrument are live explanations for the trend. The rotation keeps the dates and window sizes where they are and shifts the report block against them, so composition-by-calendar survives it and remains a rival explanation. The third panel is a volatility diagnostic on the daily residual, not an early-warning test: no run-up window, no surrogate family, no declared transition.
